BUSINESS PROCESS MODELLING ASSIGNMENT

Design an End-to-End Business Process using BPMN 2.0

Business Context

Organization

Meesho is an Indian e-commerce platform that connects small resellers, individual buyers, and a large base of unbranded sellers through a mobile-first marketplace. Unlike inventory led e-commerce players, Meesho operates a zero-commission, seller-driven marketplace model and relies heavily on third-party logistics (3PL) partners for pickup and last-mile delivery.

Process

The process selected for modelling is the Online Order Fulfilment process, the end-to-end journey from the moment a customer places an order on the Meesho app to the point the order is either delivered successfully, cancelled, rejected, or refunded.

Purpose

The purpose of documenting this process is to give Meesho's management and the ERP implementation team a clear, standardized view of how an order moves across the customer, the platform, the seller, and the logistics partner, so that the process can be automated within an ERP/OMS (Order Management System) environment, with clearly defined system checkpoints, approvals, and exception handling.

Business Problem

Meesho's fulfilment process today spans multiple independent parties viz. the customer, thousands of unorganized sellers, and several logistics partners.This creates visibility gaps, delayed order confirmations, inconsistent packaging/quality checks, and a high rate of failed first-attempt deliveries (common in COD-heavy, tier-2/tier-3 markets). Management wants to identify where automation, parallel processing, and system-driven validations (stock, payment, quality) can reduce cycle time, cut return/RTO (Return-to-Origin) rates, and improve the customer experience before deciding on ERP/OMS implementation.

Process Scope

Start Event: Customer places an order and completes payment on the Meesho mobile app / website.

End Event: (1) Order Delivered Successfully (2) Order Rejected — invalid payment (3) Order Cancelled — stock unavailable (4) Order Refunded — failed delivery / return

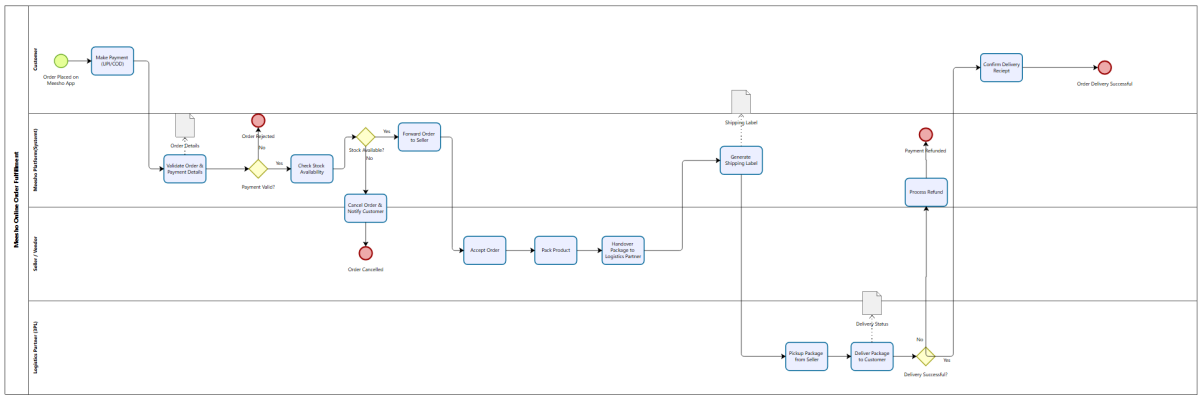

Process Trigger: A customer browsing the Meesho catalogue selects a product and confirms checkout (COD or prepaid).

Expected Output: A validated order that is packed, dispatched, and delivered to the customer's address, with the customer notified at each milestone; alternatively, a clean cancellation, rejection, or refund with the customer notified.

Primary Stakeholder: Customer (buyer placing the order)

Supporting Stakeholders: Meesho Platform/Operations team (order & payment validation, seller coordination), Seller/Vendor (packing & handover), Logistics Partner / 3PL (pickup, transit, last-mile delivery), Finance team (refund processing)

BPMN Diagram

Business Rules

- **Rule 1**: Orders with failed or unverifiable payment are automatically rejected and the customer is notified within 15 minutes.
- **Rule 2**: If the ordered SKU is out of stock at the seller's end, the order must be auto cancelled within 2 hours and the customer notified with a full refund.
- **Rule 3**: The seller must accept, pack, and hand over the order to the logistics partner within 48 hours of order confirmation, failing which the order is auto escalated to the Meesho Operations team.
- **Rule 4**: A package that fails quality inspection (damaged, wrong item, or incomplete) during packing must be re-packed before handover, it cannot be shipped without passing this check.
- **Rule 5**: If a delivery attempt fails twice, the logistics partner initiates an RTO (Return to Origin) and Meesho processes a refund to the customer within 7 business days of the returned package being received.

Process Improvement Suggestions

1. **Automate Stock and Payment Validation**

Integrate Meesho's Order Management System with seller's inventory feed and the payment gateway so that stock availability and payment validation checks can be done real-time at the time of checkout. This reduces the volume of orders that are cancelled post checkout.

2. **Enable parallel processing of Shipping Label generation and Packaging**

Currently, shipping label is generated after seller hands over the package to the logistics partner. If we can generate the shipping label in parallel with the seller's packaging activity (as soon as the order is forwarded), it would shorten the pickup to dispatch cycle time.

3. **Consolidated Returns & Quality-Check Analytics Loop**

Feed data from failed quality checks (at packing) and delivery failures/RTOs back into a single seller-performance dashboard within the Order Management System. Today these two exception paths are handled in isolation, packing rejections by the seller, delivery failures by the 3PL, with no shared analytics. Consolidating them would let Meesho flag underperforming sellers (high repack rates) and risky pin codes (high RTO rates) automatically. Using these insights, they can start targeted seller coaching or COD eligibility restrictions in certain areas. This will help mitigate losses incurred by Meesho.
